1.5.2 Country–Year Aggregation

C-variables, ratio/percentage variables, and High-Level/Mid-Level Democracy indices are aggregated from the country-date level to the country-year level by the day-weighted mean. Ordinal versions of C-variables are aggregated to the country-year level by taking the last observation in the year. Ordinal A-variables and A*-variables are aggregated by taking the last observation in the year with one exception: event-specific dichotomies or event-specific ordinal variables, which mostly concerns elections or election related data, are aggregated by max (meaning the highest observed value for a given year is retained) to reflect that an "event" of the coded type occurred within the year.

1.5.3 Open source code

Since version 11 of the V-Dem dataset we have released the code that is used for creating the V-Dem datasets to the public at `https://github.com/vdeminstitute/dataset_construction`.
